Database Management System

Sumayyea Salahuddin (Lecturer)
Dept. of Computer Systems Eng.
UET Peshawar

Objectives

- Advance SQL (Part II)
 - Stored Program
 - Stored Procedures
 - Stored Functions
 - Triggers
 - Why use Stored Programs?
 - A Quick Tour via Examples
 - Resources

Stored Programs

- Also known as stored module or stored routines.
- It is stored within and executes within database server. On execution, it is executed within the memory address of a database server process or thread
- Three major types of MySQL stored programs:
 - Stored Procedures
 - The most common type of stored program
 - Generic program unit that is executed on request & that can accept multiple input and output parameters
 - Stored Functions
 - Similar to stored procedure but their execution results in return of a single value
 - It can be used within a standard SQL statement.
 - Triggers

Stored Programs (Cont.)

Triggers

- These are activated in response to, or are triggered by an activity within the database.
- Invoked in response to a DML operation (insert, update, delete) against a database table
- These can be used for data validation.

Why use Stored Procedures?

- 1) Use of stored programs can lead to a more secure database.
- 2) Stored programs offer a mechanism to abstract data access routines, which can improve the maintainability of your code as underlying data structures evolve.
- 3) Stored programs can reduce network traffic, as program can work on data from within the server, rather than having to transfer data across the network.
- 4) Stored programs can be used to implement common routines accessible from multiple applications possibly using otherwise incompatible frameworks executed either within or from outside the database server.
- 5) Database-centric logic can be isolated in stored programs & implemented by programmers with more specialized, database experience.
- 6) The use of stored programs can, under some circumstances, improve the portability of your application.

Why use Stored Procedures? (Cont.)

 These can improve the performance, security, maintainability, and reliability of applications.

Stored Procedure – Example 1

Embedding SQL in a stored program

```
1 CREATE PROCEDURE example1( )
2 BEGIN
     DECLARE
                                   i did not od this part
 1 book count INTEGER;
     SELECT COUNT (*)
       INTO 1 book count
       FROM books
      WHERE author LIKE '%HARRISON, GUY%';
10
     SELECT CONCAT('Guy has written (or co-written) ',
11
            1 book count ,
            'books.');
12
13
14
    -- Oh, and I changed my name, so...
      UPDATE books
1.5
16
         SET author = REPLACE (author, 'GUY', 'GUILLERMO')
       WHERE author LIKE '%HARRISON, GUY%';
17
18
19 END
```

Stored Procedure – Example 1 (Cont.)

Example Explanation

Line (s)	Explanation	
1	This section, the header of the program, defines the name (example1) and type (PROCEDURE) of our stored program.	
2	This BEGIN keyword indicates the beginning of the <i>program body</i> , which contains the declarations and executable code that constitutes the procedure. If the program body contains more than one statement (as in this program), the multiple statements are enclosed in a BEGIN-END block.	
3	Here we declare an integer variable to hold the results of a database query that we will subsequently execute.	
5-8	We run a query to determine the total number of books that Guy has authored or coauthored. Pay special attention to line 6: the INTO clause that appears within the SELECT serves as the "bridge" from the database to the local stored program language variables.	
10- 12	We use a simple SELECT statement (e.g., one without a FROM clause) to display the number of books. When we issue a SELECT without an INTO clause, the results are returned directly to the calling program. This is a non-ANSI extension that allows stored programs to easily return result sets (a common scenario when working with SQL Server and other RDBMSs).	
14	This single-line comment explains the purpose of the UPDATE.	
15- 17	Guy has decided to change the spelling of his first name to "Guillermo" he's probably being stalked by fans of his Oracle bookso we issue an UPDATE against the books table. We take advantage of the built-in REPLACE function to locate all instances of "GUY" and replace them with "GUILLERMO".	

Stored Procedure – Example 2

Stored Procedure with Control and Conditional Logic

```
CREATE PROCEDURE pay out balance
2
        (account id in INT)
   BEGIN
4
6
   DECLARE 1 balance remaining NUMERIC(10,2);
                                                             Idid not do this part
   payout loop:LOOP
     SET 1 balance remaining = account balance(account id in);
10
      IF 1 balance remaining < 1000 THEN
11
      LEAVE payout loop;
12
13
14
      ELSE
15
        CALL apply balance (account id in, 1 balance remaining);
16
      END IF;
17
18
   END LOOP;
19
20 END
```

Stored Procedure – Example 2 (Cont.)

Example Explanation

Line (s)	Explanation	
1-3	This is the header of our procedure; line 2 contains the parameter list of the procedure, which in this case consists of a single incoming value (the identification number of the account).	
6	Declare a variable to hold the remaining balance for an account.	
8-18	This simple loop (named so because it is started simply with the keyword LOOP, as opposed to WHILE OF REPEAT) iterates until the account balance falls below 1000. In MySQL, we can name the loop (line 8, payout_loop), which then allows us to use the LEAVE statement (see line 12) to terminate that particular loop. After leaving a loop, the MySQL engine will then proceed to the next executable statement following the END LOOP; statement (line 18).	
9	Call the account_balance function (which must have been previously defined) to retrieve the balance for this account. MySQL allows you to call a stored program from within another stored program, thus facilitating reuse of code. Since this program is a function, it returns a value and can therefore be called from within a MySQL SET assignment.	
11- 16	This IF statement causes the loop to terminate if the account balance falls below \$1,000. Otherwise (the ELSE clause), it applies the balance to the next charge. You can construct much more complex Boolean expressions with ELSEIF clauses, as well.	
15	Call the apply_balance procedure. This is an example of code reuse; rather than repeating the logic of apply_balance in this procedure, we call a common routine.	

Stored Procedure – Example 3

Error Handling in a Stored Program

```
I did not do this part
  CREATE PROCEDURE sp product code
       (in product code VARCHAR(2),
        in product name VARCHAR(30))
4
  BEGIN
6
7
     DECLARE 1 dupkey indicator INT DEFAULT 0;
     DECLARE duplicate key CONDITION FOR 1062;
8
9
     DECLARE CONTINUE HANDLER FOR duplicate key SET 1 dupkey indicator =1;
10
11
    INSERT INTO product codes (product code, product name)
12
    VALUES (in product code, in product name);
13
    IF 1 dupkey indicator THEN
14
15
   UPDATE product codes
16
          SET product name=in product name
17
        WHERE product code=in product code;
18
     END IF;
19
20 END
```

Stored Procedure – Example 3 (Cont.)

Example Explanation

Line (s)	Explanation	
1-4	This is the header of the stored procedure, accepting two IN parameters: product code and product name.	
7	Declare a variable that we will use to detect the occurrence of a duplicate key violation. The variable is initialized with a value of 0 (false); subsequent code will ensure that it gets set to a value of 1 (true) only if a duplicate key violation takes place.	
8	Define a named condition, duplicate_key , that is associated with MySQL error 1062. While this step is not strictly necessary, we recommend that you define such conditions to improve the readability of your code (you can now reference the error by name instead of by number).	
9	Define an error handler that will trap the duplicate key error and then set the value of the variable <code>l_dupkey_indicator</code> to 1 (true) if a duplicate key violation is encountered anywhere in the subsequent code.	
11- 12	Insert a new product with the user-provided code and name.	
14	Check the value of the <code>l_dupkey_indicator</code> variable. If it is still 0, then the <code>INSERT</code> was successful and we are done. If the value has been changed to 1 (true), we know that there has been a duplicate key violation. We then run the <code>UPDATE</code> statement in lines 15-17 to change the name of the product with the specified code.	

Stored Procedure – Example 4

```
mysql> delimiter /
mysql> create procedure tour_entry()
    -> begin
    -> select TourName, TourType, year
    -> from tour natural join entry;
    -> end/
Query OK, 0 rows affected (0.12 sec)
mysql> delimiter ;
mysql> call tour_entry();
                TourType |
  TourName
                           year
              | Social
  Leeston
                           2013
              | Social
  Leeston
                           2014
              Social
  Kaiapoi
                          2014
  WestCoast | Social
                         2014
  Canterburry | Open
                           2012
  Canterburry | Open
                           2014
  Otago
                           2013
              Open
                           2014
  Otago
                Open
8 rows in set (0.09 sec)
```

Stored Procedure – Example 5

```
delimiter /
create procedure member_contact(in fn varchar(15), in ln varchar(15))
begin
select Phone from member
where FirstName = fn and LastName = ln;
end/

mysql> call member_contact('Brenda', 'Nolan');
+-----+
| Phone |
+-----+
| 442649 |
+-----+
| row in set (0.00 sec)
```

Stored Function to Calculate Age from Date of Birth

```
1 CREATE FUNCTION f age (in dob datetime) returns int
   NO SQL
3 BEGIN
  DECLARE 1 age INT;
  IF DATE_FORMAT(NOW( ),'00-%m-%d') >= DATE_FORMAT(in dob,'00-%m-%d') THEN
       -- This person has had a birthday this year
      SET 1 age=DATE FORMAT(NOW( ), '%Y')-DATE FORMAT(in dob, '%Y');
    ELSE
      -- Yet to have a birthday this year
        SET 1 age=DATE FORMAT(NOW( ),'%Y')-DATE FORMAT(in dob,'%Y')-1;
10
11
    END IF;
12
    RETURN(1 age);
END;
```

Stored Function – Example 1 (Cont.)

Example Explanation

Lines (s)	Explanation	
1	Define the function: its name, input parameters (a single date), and return value (an integer).	
2	This function contains no SQL statements. There's some controversy about the use of this clause see $\underline{\text{Chapters 3}}$ and $\underline{\text{10}}$ for more discussion.	
4	Declare a local variable to hold the results of our age calculation.	
5-11	This if-else-end if block checks to see if the birth date in question has occurred yet this year.	
7	If the birth date has, in fact, passed in the current year, we can calculate the age by simply subtracting the year of birth from the current year.	
10	Otherwise (i.e., the birth date is yet to occur this year), we need to subtract an additional year from our age calculation.	
12	Return the age as calculated to the calling program.	

Using a Stored Function within a SQL Statement

```
mysql> create function memberDuration (d year) returns int
   -> begin
   -> declare a int;
   -> select year(current_date) into a;
   \rightarrow set a = a - d;
   -> return(a):
   -> end/
Query OK, 0 rows affected (0.00 sec)
        | MemberDuration |
          Name
          Melissa McKenzie
          Michael Stone
          Brenda Nolan
          Helen Branch
          Sarah Beck
          Thomas Spence
          Sandra Burton
          William Cooper
```

10 rows in set (0.00 sec)

Barbara Olson Robert Pollard

```
mysql> delimiter /
mysql> create function member_con(fn varchar(15),
    -> In varchar(15)) returns int(11)
    -> begin
    -> declare contact int default 0;
    -> select Phone into contact
    -> from member
    -> where FirstName = fn and LastName = ln;
    -> return contact;
    -> end/
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
mýsql> select memb́er_con('Brenda', 'Nolan');
 member_con('Brenda', 'Nolan')
1 row in set (0.00 sec)
```

Triggers

Basic Trigger Syntax

```
CREATE

TRIGGER `event_name` BEFORE/AFTER INSERT/UPDATE/DELETE

ON `database`.`table`

FOR EACH ROW BEGIN

-- trigger body

-- this code is applied to every

-- inserted/updated/deleted row

END;
```

Triggers – Example 1

Trigger to Maintain a Derived Column Value

```
CREATE TRIGGER employees trg bu
        BEFORE UPDATE ON employees
2
3
        FOR EACH ROW
4
     BEGIN
       IF NEW.salary <50000 THEN
5
         SET NEW.contrib 401K=500;
6
7
      ELSE
        SET NEW.contrib 401K=500+(NEW.salary-50000) *.01;
      END IF;
10
   END
```

Triggers – Example 1 (Cont.)

Example Explanation

Line (s)	Explanation	
1	A trigger has a unique name. Typically, you will want to name the trigger so as to reveal its nature. For example, the "bu" in the trigger's name indicates that this is a BEFORE UPDATE TRIgger.	
2	Define the conditions that will cause the trigger to fire. In this case, the trigger code will execute prior to an update statement on the employees table.	
3	FOR EACH ROW indicates that the trigger code will be executed once for each row being affected by the DML statement. This clause is mandatory in the current MySQL 5 trigger implementation.	
4-10	This BEGIN-END block defines the code that will run when the trigger is fired.	
5-9	Automatically populate the <code>contrib_401k</code> column in the <code>employees</code> table. If the new value for the <code>salary</code> column is less than 50000, the <code>contrib401k</code> column will be set to 500. Otherwise, the value will be calculated as shown in line 8.	

Triggers – Example 2

```
mysql> select * from employee_psh;
 emp_id | emp_name | emp_job
                                             dep_ID | emp_domicile
                                                      Peshawar
                                                 10 l
           BCA
                      Lecturer
                     | Assitant Professor
                                                      Peshawar
          XYZ
                                                 10
                                                 50
          CVA
                     Lecturer
                                                      Peshawar
                    | Assistant Professor
                                                 50 l
          VAC
                                                     Peshawar
      11
                     | Assistant Professor
                                                     Peshawar
          FGJ
      16
          JKF
                     | Lecturer
                                                 60 | Peshawar
                                                 50 l
                                                      Mardan
                     Lecturer
           CVA
7 rows in set (0.12 sec)
mysql> alter table employee_psh add column salary float;
Query OK, 0 rows affected (\overline{0}.57 \text{ sec})
Records: 0 Duplicates: 0 Warnings: 0
mysql> alter table employee_psh add column bonus float;
Query OK, 0 rows affected (0.51 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Triggers – Example 2 (Cont.)

```
mysql> delimiter /
salary | bonus
                   mysql> create trigger emp_bonus
                       -> before update on employee_psh
  NULL
           NULL
                       -> for each row
  NULL
           NULL
                       -> begin
                       -> if new.salary < 25000 then
  NULL
           NULL
                       -> set new.bonus = 500;
  NULL
           NULL
                       -> else
  NULL
           NULL
                       \rightarrow set new.bonus = 500 + (new.salary*0.05);
  NULL
           NULL
                       -> end if:
  NULL
           NULL
                       -> end/
                   Query OK, 0 rows affected (0.18 sec)
```

```
mysql> update employee_psh
    -> set salary = 105000
    -> where emp_id = 3;
Query OK, 1 row affected (0.09 sec)
Rows matched: 1 Changed: 1 Warnings: 0
```

salary	bonus
24000 105000 NULL NULL NULL NULL NULL	500 5750 NULL NULL NULL NULL
